Chapter 1

Introduction

In this document you will find some exercises with the tidyverse R packages. They are mainly based on the nycflights13 data, taken from the nycflights13 package.

1.1 Introduction to nycflights13 data

The nycflights13 package contains information about all flights that departed from NYC (e.g. EWR, JFK and LGA) in 2013: 336,776 flights in total.

```
require(nycflights13)
ls(pos = "package:nycflights13")

## [1] "airlines" "airports" "flights" "planes" "weather"
```

To help understand what causes delays, it includes a number of useful datasets:

- flights: information about all flights that departed from NYC
- weather: hourly meterological data for each airport;
- planes: construction information about each plane;
- airports: airport names and locations;
- airlines: translation between two letter carrier codes and names.

1.1.1 flights

This dataset contains on-time data for all flights that departed from NYC (i.e. JFK, LGA or EWR) in 2013. The data frame has 16 variables and 336776 observations. The variables are organised as follow:

- Date of departure: year, month, day;
- Departure and arrival times (local tz): dep_time, arr_time;
- Departure and arrival delays, in minutes: dep_delay, arr_delay (negative times represent early departures/arrivals);
- Time of departure broken in to hour and minutes: hour, minute;
- Two letter carrier abbreviation: carrier;
- Plane tail number: tailnum;
- Flight number: flight;
- Origin and destination: origin, dest;
- Amount of time spent in the air: air_time;
- Distance flown: distance.

```

```

1.1.3 airports

\$ tz

\$ dst : chr "A" "A" "A" "A" ...

This dataset contains useful metadata about airports, that is:

- FAA airport code: faa;
- Usual name of the aiport: name;
- Location of airport: lat, lon;
- Altitude (in feet): alt;
- Timezone offset from GMT: tz;
- Daylight savings time zone: dst A = Standard US DST: starts on the second Sunday of March, ends on the first Sunday of November U = unknown N = no dst

The data frame has 7 variables and 1397 observations.

1.1.4 planes

This dataset contains plane metadata for all plane tailnumbers found in the FAA aircraft registry (American Airways (AA) and Envoy Air (MQ) report fleet numbers rather than tail numbers). The data frame has 9 variables and 3322 observations. The variables are organised as follow:

- Tail number: tailnum;
- Year manufactured: year;
- Type of plane: type;
- Manufacturer and model: manufacturer, model;
- Number of engines and seats: engines, seats;
- Average cruising speed in mph: speed;
- Type of engine: engine.

1.1.5 weather

\$ engine

This dataset is about hourly meterological data for LGA, JFK and EWR. The data frame has 14 variables and 8719 observations. The variables are organised as follow:

- Weather station: origin (named origin to faciliate merging with flights data);
- Time of recording: year, month, day, hour;
- Temperature and dewpoint in F: temp, dewp;
- Relative humidity: humid;
- Wind direction (in degrees), speed and gust speed (in mph): wind_dir, wind_speed, wind_gust;

- Preciptation, in inches: precip;
- Sea level pressure in millibars: pressure;
- Visibility in miles: visib.

Chapter 2

Verb functions

In this section you will find exercises on the basic verbs of data manipulating provided by dplyr:

```
    select();
    filter();
    arrange();
    mutate();
    summarise().
```

2.1 select() and its friends

Note: all the exercises of this section are based on the flights dataset.

```
require(tidyverse)
require(nycflights13)
```

2.1.1 Exercise 1

Extract the following information about flights:

- month;
- day;
- $\bullet \ \ air_time;$
- distance.

```
# require(nycflights13)
data(flights)
flights %>% select(month, day, air_time, distance)
## # A tibble: 336,776 x 4
##
      month
               day air_time distance

2.4 mutate() and its friends

Note: all the exercises of this section are based on the flights dataset. Times are in minutes and distances are in miles.

```
require(tidyverse)
require(nycflights13)
```

2.4.1 Exercise 1

Add the following new variables to the flights dataset:

- the gained time in minutes, defined as the difference between delay at departure and delay at arrival;
- the speed in miles per hour (distance / air time * 60).

Show only the following variables: delay at departure, delay at arrival, distance, air time and the two new variables (gained time and speed).

```
flights %>% mutate(gained_time = arr_delay - dep_delay, speed = distance/air_time*60)
## # A tibble: 336,776 x 21

2.4.3 Exercise 3

After sorting flights in chronological order, for each flight calculate the difference between its delay at arrival and the delay at arrival of the immediately previous flight. Have R to show only the delay variables (delay at departure, delay at arrival and the new variable).

```
flights %>%
  arrange(year, month, day) %>%
```

```
mutate(lead_arr_delay = lead(arr_delay), delta_delay = lead_arr_delay - arr_delay) %>%
select(dep_delay, arr_delay, delta_delay)
```

```
## # A tibble: 336,776 x 3
##
      dep_delay arr_delay delta_delay

2.5. SUMMARISE() 27

2.5 summarise()

Note: all the exercises of this section are based on the flights dataset.

```
require(tidyverse)
require(nycflights13)
```

2.5.1 Exercise 1

Calculate minimum, mean and maximum delay at arrival.

2.5.2 Exercise 2

Calculate minimum, mean and maximum delay at arrival for flights in January.

2.5.3 Exercise 3

Calculate the number of flights are contained in the dataset

```
flights %>%
  summarise(n_flights = n())
```

A tibble: 1 x 1 ## n_flights ## <int> ## 1 336776

Chapter 3

Grouping data

3.1 group_by()

Note: all the exercises of this section are based on the flights dataset.

```
library(tidyverse)
library(nycflights13)
```

3.1.1 Exercise 1

Calculate number of flights, minimum, mean and maximum delay at arrival for flights by month.

```
flights %>%
  group_by(month) %>%
  summarise(n_flights = n(),
    min_arr_delay = min(arr_delay, na.rm = T),
    mean_arr_delay = mean(arr_delay, na.rm = T),
    max_arr_delay = max(arr_delay, na.rm = T))

4.1.4 Exercise 4

Redo the previous exercise putting mean and standard deviation in two different columns (hint: use summarise()).

4.1. DO 35

36 CHAPTER 4. DO

Combining data

5.1 Joins: inner_join(), left_join(), right_join(), etc.

Note: all the exercises of this section are based on flights, airlines, airports or planes datasets.

```
library(dplyr)
library(nycflights13)
```

5.1.1 Exercise 1

Keep only the following variables of the flights dataset: month, day, hour, origin, destination and carrier. Save this dataset in a data frame and call it flights_red. Through a proper join command, add the carrier name to flights_red (this piece of information is available in airlines).

```
flights_red <- flights %>%
 select(month, day, hour, origin, dest, carrier)
right_join(flights_red, airlines)
## Joining, by = "carrier"
## # A tibble: 336,776 x 7
##
     month day hour origin dest carrier

```

5.1.2 Exercise 2

Through a proper join command, add name, latitude, longitude and altitude of the origin airport to flights_red (these pieces of information are available in airports). Do the same also for the destination airport. (If you are able to, try to keep variables about both origin and destination airports in the same final dataset).

```
flights_red %>% left_join(airports, c("origin" = "faa"))
```

```

JFK

5.1.6 Exercise 6

1

10

... with 7,592 more rows

23

10

Sort the planes dataset by increasing year. Then create two datasets: the first will deal with planes older than 2000; the second will deal with planes of 2000 or newer. Finally create a unique dataset where the first rows will deal with the newest planes, whereas the last rows will deal with the oldest planes.

PSE

B6

```
planes_old <- planes %>%
  arrange(year) %>%
  filter(year <= 2000)</pre>
```

```
planes_young <- planes %>%
  arrange(year) %>%
  filter(year > 2000)
```

planes_old %>% bind_rows(planes_young)

Tidy data with tidyr

6.1 tidyr

```
library(tidyverse)
```

6.1.1 Exercise 1

Consider the following dataset:

```
heartrate_wide <- data.frame(</pre>
  name = c("Aldo", "Giovanni", "Giacomo"),
  surname = c("Baglio", "Storti", "Poretti"),
  morning = c(67, 80, 64),
  afternoon = c(56, 90, 50)
heartrate_wide
         name surname morning afternoon
## 1
         Aldo Baglio
                            67
                                      56
## 2 Giovanni Storti
                            80
                                      90
## 3 Giacomo Poretti
                            64
                                      50
```

It represents the heart rate measured on three patients in the morning and in the afternoon. The dataset is in the wide format: change it to the long format through a proper tidyr function. Save the result in a data frame and call it heartrate_long.

```
heartrate_long <- gather(heartrate_wide, key = "when", value = "value", 3:4)
```

6.1.2 Exercise 2

Starting from heartrate_long, come back to a dataset in a wide format through a proper tidyr function. The result should be obviously equal to heartrate_wide.

```
## name surname afternoon morning
## 1 Aldo Baglio 56 67
## 2 Giacomo Poretti 50 64
## 3 Giovanni Storti 90 80
```

6.1.3 Exercise 3

Consider the dataset heartrate_wide and unite name and surname of the patients in a unique column through a proper tidyr function. Save the result in a new data frame called heartrate_united.

```
heartrate_united <- heartrate_wide %>% unite(name_surname, name, surname)
```

6.1.4 Exercise 4

Starting from heartrate_united, come back to a dataset where name and surname are in two different columns through a proper tidyr function. The result should be obviously equal to heartrate_wide.

```
heartrate_united %>%
separate(name_surname, c("name", "surname"))

## name surname morning afternoon

## 1 Aldo Baglio 67 56

## 2 Giovanni Storti 80 90

## 3 Giacomo Poretti 64 50
```

Handling Missing values

7.1 Data import: set working directory

Some of the data that will be used in this exercises are contained in the data folder. Hence you should set your working directory in the *data* folder, using setwd() function, like in this example:

```
setwd("~/Documents/datamanage/exercises/data)
```

You will work inside this folder.

```
library(tidyverse)
```

7.1.1 Exercise 1

Consider the following dataset:

It represents the heart rate measured on three patients in the morning, in the afternoon and in the evening. Make explicit any implicit missing value. How many missing values do you see?

```
heartrate %>% complete(surname, when, fill=list(name="Aldo"))
```

```
## # A tibble: 9 x 4
## surname when name heartrate
##
     <fctr> <fctr> <fctr> <fctr> <fctr>
## 1 Baglio afternoon
                       Aldo
                                   56
                     Aldo
## 2 Baglio evening
                                   NA
## 3 Baglio morning
                        Aldo
                                    67
## 4 Poretti afternoon Giacomo
                                    50
## 5 Poretti evening Giacomo
                                    85
## 6 Poretti morning Giacomo
                                    64
## 7 Storti afternoon Giovanni
                                    90
## 8 Storti evening Giovanni
                                    60
## 9 Storti morning Giovanni
                                    80
# one missing value
# alternatively:
# heartrate %>%
# complete(surname, when) %>%
# fill(name)
```

7.1.2 Exercise 2

Import data in the file marks.Rdta. Missing values have been recorded as ".". What's the percentage of missing values in the data? Replace them with NA and drop them.

```
load("marks.Rdata")
marks_NA <- na_if(marks, ".")</pre>
marks_NA %>%
  filter(is.na(marks)) %>%
  summarise(n())/30
            n()
## 1 0.06666667
# 6.7% of missing values
marks_NA %>% drop_na()
## # A tibble: 28 x 1
##
     marks
##
      <chr>
## 1
         25
## 2
         21
## 3
         26
```

```
##
   4
        23
## 5
        23
## 6
        24
## 7
        22
## 8
        24
## 9
        23
## 10
        26
## # ... with 18 more rows
```

7.1.3 Exercise 3

Import the data heartrate_NA.Rdta. Consider all the missing values you find and replace them using the function fill() when possible.

```
load("heartrate_NA.Rdata")
heartrate_NA %>%
  na_if( "") %>%
  fill(name, surname)
## # A tibble: 9 x 4
##
        name surname when heartrate
<chr> <chr> <chr> <chr>
        name surname
                           when heartrate
##
         Aldo Baglio morning
## 1
                                         67
         Aldo Baglio afternoon
## 2
                                         56
## 3
         Aldo Baglio evening
                                         67
## 4 Giovanni Storti morning
                                         80
## 5 Giovanni Storti afternoon
## 6 Giovanni Storti evening
                                         90
                                         60
                                         64
## 7 Giacomo Poretti morning
                                         50
## 8 Giacomo Poretti afternoon
## 9 Giacomo Poretti evening
                                         85
```

Dates with lubridate

8.1 lubridate

Note: all the exercises of this section are based on the flights dataset.

```
require(tidyverse)
require(lubridate)
require(nycflights13)
```

8.1.1 Exercise 1

Using the flights data, build the variable dep_date based on the variables year, month and day. First use the function unite() and then the parsing function ydm(). Select only the new variable and save the new data frame called flights_date.

```
flights_date <- flights %>%
   unite(date, year, month, day) %>%
   mutate(date = ymd(date)) %>%
   select(date)
```

8.1.2 Exercise 2

Using the dataset, shift all flights by two months. Save it in a separate data frame called flights_date_2.

```
flights_date_2 <- flights_date %>% mutate(date2 = date + months(2))
```

8.1.3 Exercise 3

Take the new date (2 months ahead) and substruct the original variable date. flights_date_2.

flights_date_2 %>% mutate(date2-date)

```
## # A tibble: 336,776 x 3
           date
                   date2 `date2 - date`
##
##
         <date>
                    <date>
                                 <time>
## 1 2013-01-01 2013-03-01
                                59 days
   2 2013-01-01 2013-03-01
                                 59 days
## 3 2013-01-01 2013-03-01
                                59 days

Manipulating strings with stringr

9.1 Data import: set working directory

In this section you will work with data are contained in the data folder. Hence you should set your working directory in the *data* folder, using setwd() function, like in this example:

```
setwd("~/Documents/datamanage/exercises/data)
```

You will work inside this folder.

```
library(tidyverse)
library(stringr)
```

9.1.1 Exercise 1

Import the data aire_milano_strings.txt which is a tab delimited file. Find how China has been codified (notice that the file is in Italian) and manipulate that string as you find more confortable for you. Save the results in a new tibble.

```
## Parsed with column specification:
## cols(
## Residenza = col_character(),
## MotivoIscrizioneEstero = col_character(),
## Num = col_integer()
## )

aire %>% filter(str_detect(Residenza, c("Cina"))) # not recorded as Cina
## # A tibble: 0 x 3
## # ... with 3 variables: Residenza <chr>, MotivoIscrizioneEstero <chr>,
## # Num <int>
```

```
aire %>% filter(str_detect(Residenza, c("cina"))) # not recorded as cina
## # A tibble: 0 x 3
## # ... with 3 variables: Residenza <chr>, MotivoIscrizioneEstero <chr>,
## #
     Num <int>
aire %>% filter(str_detect(Residenza, c("Cin")))
## # A tibble: 5 x 3
##
                Residenza
                              MotivoIscrizioneEstero
##
                     <chr>
                                               <chr> <int>
## 1 Cinese, Rep. Popolare
                                     all'emigrazione
                                                       535
## 2 Cinese, Rep. Popolare per acquisto cittadinanza
                                                        14
## 3 Cinese, Rep. Popolare
                                                       119
                                         per nascita
## 4 Cinese, Rep. Popolare per residenza all'estero
                                                        26
## 5 Cinese, Rep. Popolare
                               trasferimento da AIRE
                                                        10
aire_clean <- aire %>% mutate(Residenza,
                              Residenza = str_replace(Residenza, c("Cinese, Rep. Popolare")
                                                       "Cina"))
```

9.1.2 Exercise 2

Using the data modified in exercise 1, find all the countries whose names contain non-alphanumeric characters. Identify what kind of characters they contain.

```
str_extract(aire_clean$Residenza, "[[:punct:]]")
```

9.1.3 Exercise 3

Consider now the column with information on the reason for migrating. Count how many different reasons there are and notice that citizenship was recorded in two slightly different ways: "acquisto cittadinanza" and "per acquisto cittadinanza". Replace one of them so that they are the same.

trasferimento da AIRE

per sentenza

6

7

```
## 4
        acquisto cittadinanza
## 5
       per matrimonio
## 6 trasferimento da AIRE
## 7 per acquisto cittadinanza
## 8
                per sentenza
aire_clean <- aire_clean %>%
 mutate(MotivoIscrizioneEstero = str_replace(MotivoIscrizioneEstero,
                                           c("^acquisto cittadinanza"), "per acquisto cittadina
# now you only have 7 different levels
aire_clean %>% distinct(MotivoIscrizioneEstero)
## # A tibble: 7 x 1
##
     MotivoIscrizioneEstero
##
                     <chr>
          all'emigrazione
## 1
## 2
              per nascita
## 3 per residenza all'estero
## 4 per acquisto cittadinanza
             per matrimonio
```

Case study

10.1 Recap exercise

In this section you will use all the tools provided throughout the course. It is a simple example on real data that shows you the overall usage of the tools you were given during this course.

In the data folder you find the following three files:

- 1. rating_final.csv
- 2. chefmezcuisine.csv
- 3. userprofile.csv

These are the files you will work on in this section.

The files contain data on the rating of some restaurants in the US, their characteristics and the characteristics of the users rating them.

This exercise will guide you to first clean and combine data, and then answer questions on people's restaurant preferences.

Before starting th exercise, you should set your working directory in the *data* folder, using setwd() function, like in this example:

```
setwd("/data")
```

You will work in this folder.

10.2 Exercise

1. First of all you need to import the three files into R using the correct readr function. In order to find the correct function and to set the right options, you may explore the files by opening them in csv (check which is the separator, if there are column names, etc).

```
require(tidyverse)
# chefmozcuisine
chefmozcuisine <- read_delim("chefmozcuisine.csv", delim = ",", col_names = T)</pre>
## Parsed with column specification:
## cols(
## placeID = col_integer(),
## Rcuisine = col_character()
## )
# userprofile
userprofile <-
  read_delim("userprofile.csv", delim = ",", col_names = T)
## Parsed with column specification:
## cols(
## userID = col_character(),
## latitude = col_double(),
## longitude = col_double(),
## smoker = col_character(),
##
    drink_level = col_character(),
##
    dress_preference = col_character(),
##
    ambience = col_character(),
##
    transport = col_character(),
##
    marital_status = col_character(),
##
    hijos = col_character(),
##
    birth_year = col_integer(),
     interest = col_character(),
##
##
    personality = col_character(),
##
    religion = col_character(),
##
    activity = col_character(),
##
     color = col_character(),
##
    weight = col_integer(),
    budget = col_character(),
##
##
    height = col_double()
## )
# rating_final
rating_final <-
  read_delim("rating_final.csv",
                          delim = ",", col_names = T)
## Parsed with column specification:
## cols(
## userID = col_character(),
```

```
## placeID = col_integer(),
## rating = col_integer(),
## food_rating = col_integer(),
## service_rating = col_integer()
```

2. In order to understand what you are working on, check how many columns and rows each data frame is composed of, and check the type of the variables you are working with. If the variables type has not correctly been parsed, parse it manually. Further explore those variables that you think may be interesting for understanding different people's tastes, by for example checking how many levels they have, etc etc.

```
# chefmozcuisine
# how many rows? how many variables?
chefmozcuisine
```

```
## # A tibble: 916 x 2
##
     placeID
                      Rcuisine
##
                         <chr>
       <int>
##

             <int>
## 1
                  2
## 2
                  1
## 3
                  0
# ratings are either 0, 1 or 2
# notice that placeID is an integer value. However, it is the ID hence you will
# calculate no statistics on it. You may as well force it to a character vector.
rating_final <- rating_final %>%
 mutate(placeID = as.character(placeID))
chefmozcuisine <- chefmozcuisine %>%
 mutate(placeID = as.character(placeID))
```

3. Consider userprofile data frame. Create a new data frame containing only relevant variables for users profile. Among these, keep the variables: userID, birth_year, budget, marital_status, personality, smoker and activity. If you think there are other relevant variables, you may include them in the new data frame as well. Call the new data frame userprofile_reduced.

```
userprofile_reduced <- userprofile %>%
  select(userID, birth_year, budget, marital_status, personality, smoker, activity)
userprofile_reduced
```

```
## # A tibble: 138 x 7
##
     userID birth_year budget marital_status
                                                  personality smoker
##
      <chr>>
                <int> <chr>
                                    <chr>
                                                        <chr> <chr>
                                            thrifty-protector false
## 1 U1001

                                            thrifty-protector false
## 6 U1006
                 1989 medium
                                    single
                                                  hard-worker true
## 7 U1007
                 1989 low
                                    single
                                            thrifty-protector false
```

```
## 8 U1008 1989 low single hard-worker false
## 9 U1009 1991 medium single thrifty-protector false
## 10 U1010 1987 medium married hard-worker false
## # ... with 128 more rows, and 1 more variables: activity <chr>
```

4. Focus on the data frame userprofile_reduced. By exploring the different values recorded for budget, you may notice there are missing values. What are they recorded by? Replace all missing values with NA. Do the same for all the variables in userprofile_reduced.

```
userprofile_reduced %>%
    distinct(budget)

## # A tibble: 4 x 1

## budget

## cchr>
## 1 medium

## 2 low

## 3 ?

## 4 high

# "?" is for missing values

userprofile_reduced <- userprofile_reduced %>% na_if("?")
```

5. Note that for all users we have the year of birth but we do not have the age. As it may be easier to deal with their age, build a variable called age and drop birth_year.

```
require(lubridate)

## Loading required package: lubridate

## Loading required package: methods

##

## Attaching package: 'lubridate'

## The following object is masked from 'package:base':
##

## date
```

```
userprofile_reduced <- userprofile_reduced %>%
  mutate(age = year(today())-birth_year) %>%
  select(-birth_year)
```

6. All three data frames are now ready to use. Merge the three data frames (rating_final, userprofile_reduced and chefmoicuisine) so that you keep all rows and columns of rating and you add all the variables of chefmezcuisine and userprofile_reduced. Call the new data frame rating_all.

```
rating_all <- rating_final %>%
  left_join(userprofile_reduced) %>%
  left_join(chefmozcuisine)

## Joining, by = "userID"

## Joining, by = "placeID"
```

7. Group data by placeID and find the average rating (rating, food_rating and service_rating). Sort the results so that places with the highest average rating are at the top. Show id of such places and type of cuisine. What is the cuisine type of users' favourite restaurants?

Rcuisine	service_rating_mean	<pre>food_rating_mean</pre>	rating_mean	placeID		##
<chr></chr>	<dbl></dbl>	<dbl></dbl>	<dbl></dbl>	<chr></chr>		##

8. Find mean and standard deviation of all rating variables. Do you notice differences with regards to ratings of students as compared to people that are employed? Do you find differences in smokers and non smokers? Think of other groups of users to compare.

```
rating_all %>%
  group_by(activity) %>%
  summarise_at(vars(rating, food_rating, service_rating),
               funs(n(), mean, sd))
## # A tibble: 5 x 10
